**Aim:** detection of volcanic ash and SO₂ gas.

**Time period and area of its main application:** In case of volcanic eruption.

**Guidelines:** Optically thin ash cloud can be well detected and clearly distinguish from ice and water clouds in the Ash RGB images. Optically thick ash clouds look like thick ice clouds. However, the volcanic ash becomes rapidly optically thin. Pure SO₂ gas plumes can be well detected at low satellite viewing angles closer to the sub-satellite point than for example London or Copenhagen.

In case of very low concentrations, ash and SO₂ gas might be not seen from geo satellites, only by the sounding instruments of polar orbiting satellites. Ash RGB does not provide information on height and concentration, but it provide high temporal resolution. Volcanoes inject water vapour as well, which becomes cirrus cloud when reaching a height. Note that higher level SO₂ plumes are detected by Airmass RGB as well.

**Background**

The table shows which channels (or channel differences) are used in the Ash RGB and lists some of the land and cloud features which have typically low or high contribution to the colour beams in this RGB. Thin volcanic ash is separated from water and ice clouds by the (IR12.0-IR10.8) channel difference. SO₂ gas is detectable due to its absorption band at 8.7 µm.

</table>

Notation: IR: infrared, number: central wavelength of the channel in micrometer. Remark: The channel combination is the same as for Dust and 24 hour Microphysics RGBs, the tunings are different (not shown here).

**Benefits**

- It works both night- and daytime. (This allows to create long animations.)
- Different colours for thin volcanic ash, SO₂ gas plume and cirrus clouds (and for the mixture of ash and SO₂ gas).
- Thin volcanic ash has good colour contrast against water and ice clouds and surface features.
- SO₂ gas plume has good colour contrast against ice clouds and surface features, but close to the limb water clouds might have similar colour as pure SO₂ plume – see limitations.
- The colours of the water and ice clouds and the surface are similar (paler) to their colours in the Dust / 24 hour Microphysics RGBs.

**Limitations**

- Lower-level volcanic ash and SO₂ gas plume can be covered by higher-level clouds.
- Very thick ash clouds cannot be discriminated from ice clouds.
- In case the volcanic ash and/or SO₂ gas plume is mixed with cirrus cloud their identification might be problematic.
- The colours considerably depend on the satellite viewing angle. The colour of the water clouds turn into green towards the limb. Thus pure SO₂ gas plume can be easily separated from water clouds only at low satellite viewing angles closer to the sub-satellite point (zero latitude and longitude) than for example London or Copenhagen. In case of high satellite viewing angles Dust RGB is more appropriate for SO₂ detection.
**SEVIRI Ash RGB Quick Guide**

**Interpretation**

1. **Cloud free land**
   (Shades of blue or pink depending on the temperature and water vapour content)

2. **SO₂ gas plume**
   (Shades of bright green depending on the concentration)

3. **Thin volcanic ash**
   (Shades of red depending on the concentration)

4. **Mixed ash and SO₂ gas**
   (Shades of yellow depending on the concentrations)

5. **Water cloud**
   (Shades of greyish tan)

6. **Thick ice cloud or Thick volcanic ash cloud**
   (Shades of brown)

7. **Thin ice cloud**
   (Shades of dark blue depending on the transparency)

**Comparison to other products**
In the Ash RGB one can see both the ash (red/magenta) and the SO₂ gas plume (green). In the IR10.8 image one cannot see the SO₂ gas plume at all. In the IR10.8 image one can see the volcanic ash plume but one can not distinguish it from water or ice clouds.
